Warning
This description alone does not provide sufficient background for direct use of the instrument set. Instruction by a surgeon experienced in handling these instruments and the attendance of a VBS training in order to know the VBS instrumentation and technique is highly recommended.

### Bibliography
- 36
VBS is a safe treatment method for painful vertebral body fractures and lesions. It helps to prevent effects such as postural damage and pain caused by postural kyphosis.

VBS offers unique benefits to patients and physicians:

**Percutaneous**
The VBS stents are introduced percutaneously into the vertebral body with only a stab incision required to place the access instruments.

**Reconstructive**
The VBS system restores the loss of height in the fractured vertebral body.

**Height conserving**
Expanding the VBS stents inside the collapsed vertebra offers height restoration and conservation. The mechanical construct restores the height while at the same time offering a cavity for injection of highly viscous PMMA based bone cement cleared for use in vertebroplasty or kyphoplasty procedures.

Minimally invasive, percutaneous insertion of the Vertebral Body Stenting System
Instrument insertion through a stab incision allows performing the procedure under either local or general anaesthesia.
Restoration through balloon dilatation and stent expansion
Simultaneous dilation of the bilaterally positioned VBS Stents offers an in situ controlled and continuous expansion.

Augmentation with Vertecem V+
Vertecem V+ is a PMMA based bone cement for the treatment of vertebral compression fractures:
- Immediate injection upon mixing
- About 27 minutes of working time
- Excellent x-ray visibility

Expansion ratio up to 400%
The Vertebral Body Stenting technology offers an expansion ratio up to 400% for the reconstruction of collapsed vertebrae.

Controlled balloon dilatation with the VBS Inflation System
The applied pressure and injected volume of the mixture of saline solution and contrast medium can constantly be monitored and controlled with the help of the phosphorescent display.
AO Principles

In 1958, the AO formulated four basic principles, which have become the guidelines for internal fixation. They are:

- Anatomic reduction
- Stable fixation
- Preservation of blood supply
- Early, active mobilization

The fundamental aims of fracture treatment in the limbs and fusion of the spine are the same. But a specific goal of spine treatment is to restore as much function as possible to the injured neural elements.

**AO Principles as applied to the spine**

**Anatomic reduction**

Restoration of normal spine alignment improves the biomechanics of the spine and reduces pain by reestablishing and maintaining the natural curvature and the protective function of the spine.

**Stable fixation**

In the spine, the goal of internal fixation is to maintain not only the integrity of a mobile segment, but also to maintain the balance and the physiologic three-dimensional form of the spine. A stable spinal segment allows bony fusion at the junction of the lamina and pedicle.

**Preservation of blood supply**

The proper atraumatic technique enables minimal retraction or disturbance of the nerve roots and dura, and maintains the stability of the facet joints. The ideal surgical technique and implant design minimize damage to anatomical structures, i.e. facet capsules and soft tissue attachment remain intact, and create a physiological environment that facilitates healing.

**Early, active mobilization**

The ability to restore normal spinal anatomy may permit the immediate reduction of pain, resulting in a more active, functional patient. The reduction in pain and improved function can result when a stable spine is achieved.

---

Indications and Contraindications

**Intended use**
The VBS System is intended for the reduction of painful vertebral compression fractures and/or creation of a void in cancellous bone in the spine for the treatment of levels ranging from Th5-L5. It is intended to be used in combination with a legally-marketed PMMA based bone cement adequately indicated for use in vertebroplasty or kyphoplasty procedures.

**Note:** Refer to the manufacturer’s directions accompanying the bone cement for specific information on its use, precautions and warnings.

**Indications**
- Painful osteoporotic vertebral compression fractures without posterior wall involvement. Classified after Genant, Grade 2 and Grade 3.
- Painful vertebral compression fractures classified after the AO classification:
  - A1.1 Endplate impaction
  - A1.2 Wedge impaction fracture
  - A1.3 Vertebral body collapse
  - A3.1 Incomplete burst fracture; matter of discretion (depending on the degree of posterior wall involvement, internal fixation must be used in addition)
In combination with internal fixation:
  - A3.1 Incomplete burst fracture
  - A3.2 Burst-split fracture; matter of discretion (the extent of the gap width should not be too wide)
- B1.2 Posterior disruption predominantly ligamentous associated with type A fracture of the vertebral body
- B2.3 Posterior disruption predominantly osseous with type A fracture of the vertebral body
- Palliative treatment of osteolytic lesions located within the vertebral body with intact cortical shell. Classified after Tomita Type 1.

**Contraindications**
- Lesions requiring open anterior column reconstruction
- Acute or chronic systemic or localized spinal infections

1 Note: The long-term effects of PMMA based cements on the vertebral column are unknown. Therefore, the treating physician should weigh the benefits of the application of the PMMA based cement in younger patients against the potential risks.
Preoperative Planning

Patient assessment
Requirements for assessing the indication:
- Current X-ray images, if possible in standing position, of the thoracic and lumbar spine in two planes to assess the fracture and spinal alignment
- A spiral CT and MRI scan (ideally with STIR frequency) of the painful region of the spine
- If an MRI scan is contraindicated a bone scan may identify an acute fracture
- Ruling out another cause of pain
- Feasibility of surgery and use of anaesthesia
- Ruling out impaired clotting

Note: It is important, to treat only patients with non-consolidated fractures.

Warning: The patient should be checked for allergy to the contrast medium and stent material (CoCrWNi alloy).

Planning of stent placement
The placement of the stents should be planned based on the AP image which gives hints for the route of insertion.

Pre-planning of stent size
The stent size for the procedure can roughly be planned preoperatively via CT scan.

Intraoperative X-ray imaging
The Vertebral Body Stent must be implanted using X-ray on both planes, two C-arms, or with one freely mobile C-arm.
Preparation

Instrument preparation

Instrument Set

03.804.512S Vertebral Body Stent Access Kit

Instrument

03.804.413S VBS Inflation System

The VBS inflation system has an angled manometer that shows the pressure in the balloon in pounds/inch² (psi) and atmospheres (atm). The volume scale on the fluid chamber measures milliliters (ml).

It is necessary to prepare two VBS inflation systems.

1. Connect VBS inflation system to connector

Attach the tube of the VBS inflation system with the Luer connector to the supplied 3-way connector as shown. Rotate the knob on the 3-way connector to position the “off” indicator towards the lateral outlet (1).

2. Fill VBS inflation system

Fill the VBS inflation system with saline solution and a liquid contrast medium.

**Note:** It is essential to fill the VBS inflation system with saline/contrast agent mixture to ensure better visibility of the VBS balloon catheter during inflation. The ratio of contrast medium to saline solution should be about 1:2.

Prepare the contrast medium mixture in a cup and place the 3-way connector under the solution. Push forward on the white wings on the VBS inflation system and pull back on the handle until the plunger bottoms out. With the handle pointing upwards, tap the unit to clear the gauge portion of the inflation system of air (2).
3. Close VBS inflation system

Rotate the knob on the 3-way connector to place the “off” indicator towards the inflation system (4).

The VBS inflation system has now been prepared accordingly and can be set aside. Repeat for the second VBS inflation system.

Tip: The white wings may be pushed to unlock the plunger when large changes to the handle position are desired. The handle must be moved carefully to avoid overshooting the desired target.

Warning: If the buttons (white wings) do not return to the locked position, do not force them as this could damage the plunger. Turn the handle gently, and the buttons (white wings) will return automatically to the locked position.
Anatomical landmarks
For vertebral body augmentation with VBS, the two stents per vertebra should be placed in a symmetrical, paramedian position within the affected vertebral body to achieve optimum reduction of the spinal fracture without damaging the lateral vertebral body edges. Ideally, the distance from the compressed endplate to the stents should be about 5 mm (1).

The position of the stents needs to be planned based in preoperative imaging. Take care to achieve the planned position by determining the landmarks accordingly.

The following landmarks have to be defined on the spine:
- Both pedicles
- Spinous process
- Endplates
- Posterior wall of vertebral body
Patient Positioning

Place the patient in the prone position on a lumbar support. The table must be radiolucent in both planes.

The OR table should allow free manipulation of the C-arm over the operative site in both planes.
Access Options

There are two access options to the targeted vertebral body, depending on its anatomy:

1. **Transpedicular access**
   As a general rule, the bilateral skin incisions for the transpedicular approach are 1–2 cm lateral and up to 1 cm cranial to the centre of the pedicle (1).

2. **Extra-/Parapedicular access**
   The bilateral skin incisions for the extra-/parapedicular technique are planned according to the anatomical situation (2).

The instruments for inserting the VBS system can be placed using either a guide wire or a trocar. In the chapter “Instrument Positioning” each procedure is explained for a transpedicular and an extra-/parapedicular access.

For positioning instruments with guide wires see page 13.
For positioning instruments with trocar see page 20.
Instrument Positioning
A With Guide Wires

Instrument Set

03.804.512S  Vertebral Body Stent Access Kit

First the guide wires are positioned. The other instrumentation follows the path created by the guide wires.

Once the anatomical landmarks are detected, the guide wires can be percutaneously introduced through skin incisions using X-ray control (AP and lateral).

Either a transpedicular or extra-/parapedicular access may be selected depending on the anatomy of the vertebral body to be treated.

Note: With either access technique it is important to plan to place the two stents symmetrically towards the midline and the anterior wall of the vertebral body at a medial location. In this position the stents have room to expand without pressing against either the lateral wall, or the other stent (1).
1 Position guide wires

Make the skin incisions.

- Under AP and lateral X-ray control insert the guide wires to the superior outer pedicle quadrant using slight manual pressure.

Once the guide wires touch bone the outlines of the lateral pedicle are reached. Drive both guide wires with controlled blows from a hammer through the cortex. Cautiously advance the guide wires into the center of the vertebral body.

**Note:** The tips of the guide wires should be about and not closer than 5 mm to the anterior wall of the vertebral body. They should be positioned symmetrically and aligned in both AP and lateral views. Confirm this placement for the positioning of the stents.

**Warning:** The tips of the guide wires must not pass the midline in AP view until they have passed the posterior wall in the lateral view. When advancing the guide wires, ensure that they are not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdriving the guide wires into vascular structures beyond the anterior cortical wall.
Position working sleeves over guide wires

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar (1). Push the instrument assembly with a counterclockwise turning motion over the first guide wire (2).

**Warning:** Do not insert the working sleeve into the bone without the side-opening cannula. This could damage the working sleeve and obstruct stent insertion. Do not hammer on the side-opening cannula, cannulated trocar and working sleeve.

The working sleeve can also be placed without the mounted cannulated trocar (working sleeve with side-opening cannula over guide wire). If this method is chosen, there is more clearance between the diameter of the guide wire and the side-opening cannula to allow for minor correction in the trajectory when positioning the working sleeve. This can lead to a slight resistance when penetrating the bony vertebral body surface.
Monitor working sleeve placement under lateral X-ray control. Ensure that the tip of the working sleeve has passed the pedicle and is positioned inside the vertebral body.

**Note:** When inserting the working sleeve, carefully monitor the position of the guide wire to confirm that it is not advancing forward.

**Tip:** Pull back the side-opening cannula to verify the positioning of the working sleeve.

**Repeat on the contra-lateral side (4).**

Once both working sleeves are in place, remove the side-opening cannulae with the inserted cannulated trocar and the guide wires (5).

The working sleeves remain in the vertebral body.

**Warning:** It is important to advance the instrument assembly carefully in order to avoid any injury to the physician’s hand. Since the guide wire is longer than the combined length of the pre-mounted working sleeve with the side-opening cannula with cannulated trocar, it will protrude through the handle of the side-opening cannula (6).
A2 Extra-/Parapedicular Access

1

Position guide wires

Make the skin incisions.

Under AP and lateral X-ray control, insert the guide wires using slight manual pressure.

Insert both guide wires up to the vertebral body and drive them with controlled blows from a hammer through the cortex. Should you touch bone before reaching the vertebral body you have reached the outline of the lateral pedicle.

Note: Cautiously advance the guide wires and, if necessary, redirect in order to reach the center of the vertebral body. The tips of the guide wires should be about and not closer than 5 mm to the anterior wall of the vertebral body.

Warning: The tips of the guide wires must not pass the mid-line in AP view until they have passed the posterior wall in the lateral view. When advancing the guide wires, ensure that they are not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid over-driving the guide wires into vascular structures beyond the anterior cortical wall.
Positioning working sleeves over guide wires

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar (1). Push the instrument assembly with a counterclockwise turning motion over the first guide wire (2).

**Warning:** Do not insert the working sleeve into the bone without the side-opening cannula. This could damage the working sleeve and obstruct stent insertion. Do not hammer on the side-opening cannula, cannulated trocar and working sleeve.

The working sleeve can also be placed without the mounted cannulated trocar (working sleeve with side-opening cannula over guide wire). Then, there is more clearance between the diameter of the guide wire and the side-opening cannula to allow for minor correction in the trajectory when positioning the working sleeve. This can lead to a slight resistance when penetrating the bony vertebral body surface (3).
Monitor working sleeve placement under lateral X-ray control. Advance the tip of the working sleeve until it has penetrated the cortex and is tightly seated into the bone.

**Note:** When inserting the working sleeve, carefully monitor the position of the guide wire to confirm that it is not advancing forward.

**Tip:** Pull back the side-opening cannula to verify the positioning of the working sleeve.

**Repeat on the contra-lateral side (4).**

Once both working sleeves are in place, remove the side-opening cannulae with the inserted cannulated trocar and the guide wires (5).

The working sleeves remain in the vertebral body.

**Warning:** It is important to advance the instrument assembly carefully in order to avoid any injury to the physician’s hand. The guide wire is longer than the combined length of the instrument assembly of working sleeve and the side-opening cannula and cannulated trocar will protrude through the handle of the side-opening cannula (6).
Instrument Positioning
B With Trocars

Instrument Set

03.804.512S  Vertebral Body Stent Access Kit

When using trocars for instrument positioning, creating the pathway and positioning of the instrumentation is achieved in one step.

Either a transpedicular or extra-/parapedicular access may be selected depending on the anatomy of the vertebral body to be treated.

Note: With either access technique it is important to plan to place the two stents symmetrically towards the midline.
B1 Transpedicular Access

Positioning working sleeves

Make skin incisions.

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar. Replace the cannulated trocar by the trocar and lock it into place with a clockwise rotation (1).

Under AP and lateral X-ray control insert the instrument assembly through the skin incision to the superior outer pedicle quadrant using slight manual pressure and a counterclockwise turning motion (2). If necessary the instrument assembly can be inserted through the cortex with light impaction on the metal end of the trocar using a hammer.

**Tip:** Pull back the side-opening cannula to verify the positioning of the working sleeve.

**Warning:** When advancing the instrument assembly, ensure that the trocar tip is not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdriving the trocar tip into vascular structures beyond the anterior cortical wall.

Hold the working sleeve in place and carefully rotate and remove the trocar and the side-opening cannula. The working sleeve remains in the vertebral body.

**Repeat for the contra-lateral side (3).**

**Warning:** Do not insert the working sleeve into the bone without the side-opening cannula and trocar. This could damage the working sleeve and obstruct stent insertion.

Do not redirect the instrument assembly without removing it and re-accessing the pedicle.
B2 Extra-/Parapedicular Access

Positioning working sleeves

Make skin incisions.

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar. Replace the cannulated trocar by the trocar and lock it into place with a clockwise rotation (1).

Under AP and lateral X-ray control insert the instrument assembly through the skin incision into the vertebral body using slight manual pressure and a counterclockwise turning motion (2). If necessary the instrument assembly can be inserted through the cortex with light impaction on the metal end of the trocar using a hammer.

Advance the instrument assembly so that the opening of the working sleeve is anterior to the posterior wall of the vertebral body.

Tip: Pull back the side-opening cannula to verify the positioning of the working sleeve.

Warning: When advancing the instrument assembly, ensure that the trocar tip is not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdriving the trocar tip into vascular structures beyond the anterior cortical wall.

Hold the working sleeve in place and carefully rotate and remove the trocar and the side-opening cannula. The working sleeve remains in the vertebral body.

Repeat for the contra-lateral side (3).

Warning: Do not insert the working sleeve into the bone without the side-opening cannula and trocar. This could damage the working sleeve and obstruct stent insertion. Do not redirect the instrument assembly without removing it and re-accessing the bone.
Stent Insertion

1
Create access channel for stents

Instrument Set
03.804.512S Vertebral Body Stent Access Kit

Guide the drill (1) and afterwards the blunt plunger (2) through the working sleeves to create an access channel for the stents.

Warning: Use lateral image intensification to avoid penetrating the anterior cortex of the vertebral body. It is essential to avoid overdriving these instruments into vascular structures beyond the anterior cortical wall.

Warning: Do not use a hammer to drive the drill forward. The drill may aggressively advance with rotation.

The plunger can be driven forward with light hammer blows. Ensure that the hammer blows hit the protruding metal pin and not the plastic handle (2).

Warning: While using drill or plunger, it is important to ensure that the working sleeves do not move. Do not use the drill or plunger to manipulate or correct the direction of the working sleeve.

Repeat on the contra-lateral side.
2  
Determine length of stents

The Vertebral Body Stents are available in three sizes:

<table>
<thead>
<tr>
<th>Vertebral Body Stent</th>
<th>Article No.</th>
<th>Max (\varnothing) expanded</th>
<th>Stent length expanded</th>
<th>Release length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Small</td>
<td>09.804.500S</td>
<td>15 mm</td>
<td>13 mm</td>
<td>22 mm</td>
</tr>
<tr>
<td>Medium</td>
<td>09.804.501S</td>
<td>17 mm</td>
<td>15 mm</td>
<td>27 mm</td>
</tr>
<tr>
<td>Large</td>
<td>09.804.502S</td>
<td>17 mm</td>
<td>20 mm</td>
<td>31 mm</td>
</tr>
</tbody>
</table>

The plunger has three grooves towards the distal tip that correspond to the three stent lengths (1).

Use lateral imaging to select the length of the stent on the basis of these grooves.

From distal tip the first groove visible:
Vertebral Body Stent Small
From distal tip the second groove visible:
Vertebral Body Stent Medium
From distal tip the third groove visible:
Vertebral Body Stent Large

Establish the stent size on both sides, they may differ.

Remove the stents from the sterile packaging. Carefully remove the stiffening wire and put it aside for further use (2). If preferred, the stiffening wire can also be removed after the insertion of the balloon catheter. If this method is chosen, the creation of the vacuum has to be performed after the insertion of the balloon catheter on the patient.

There is a white marking range on the balloon catheter shaft indicating the stent and both balloon shoulders positions when inserted into the working sleeve (2).
3

Connecting balloon catheters to inflation systems and create vacuum

**Instrument**

03.804.413S VBS Inflation System

Connect the prepared VBS inflation systems with the selected stents using the Luer connector. Rotate the knob on the 3-way connector to place the “off” indicator towards the lateral side opening (1).

**Note:** It is important to ensure that all Luer connectors are securely attached. Loose connections may result in inaccurate filling volumes and pressures.

Push the white wings on the VBS inflation system forward to unlock the handle. Pull the handle all the way back, and release the wings to lock the handle in position. This pulls air out of the catheter, creating a vacuum inside it. The vacuum can be monitored on the display “vac” (2).

**Warning:** If the buttons (white wings) do not return to the locked position, do not force them as this could damage the plunger. Turn the handle gently, and the buttons (white wings) will return automatically to the locked position.
Stent Insertion

Close the balloon catheter with the 3-way connector by positioning the "off" indicator towards the catheter. This retains the vacuum inside the catheter (3).

Hold the VBS inflation system with the handle facing downward and turn the handle clockwise in order to set the volume scale to zero. This is done by turning the handle until the red ring on the plunger is precisely at "0" (4).
This flushes out the excess saline solution/contrast medium mixture and air through the lateral opening of the three-way connector (5).

**Tip:** Suspend the 3-way connector over a receptacle for all steps that involve expelling excess solution. If vacuuming on the patient, use absorbent cotton to soak up any expelled excess solution.

Rotate the knob on the 3-way connector to position the “off” indicator towards the lateral side opening. This allows flow from the VBS inflation system into the VBS balloon catheter (6).
4
Insert and deploy stents

Insert the balloon catheter with the attached stent under lateral X-ray control. The full release (initial) length of the balloon with stent is outside when the proximal end of the white marking of the catheter shaft disappears into the working sleeve. Check the position under X-ray control and confirm the desired position under AP view (1). It is important, that the whole balloon portion including the stent is positioned completely inside the vertebra and that these parts have completely passed the working sleeve.

Repeat for the contra-lateral side.

Note: Simultaneous dilation of bilateral devices is essential for optimal device performance. Once stent expansion has begun the stent cannot be undeployed or repositioned.

Warning: It is essential to use AP and lateral X-rays to track stent expansion.

Slowly increase pressure and volume by rotating the handles of the connected inflation systems in a clockwise direction on both sides.
Proceed slowly after the stents begin expanding at approx. 12 atm (2). Match the expansion bilaterally by tracking the fluid volume on the scales. When the pressure reaches 26 atm, continue dilation gradually. Wait a few seconds then slowly continue until the desired stent diameter is reached (3). The maximum stent diameter is 15 mm for the VBS Small and 17 mm for the VBS Medium and VBS Large.

Stop increasing pressure when any of the following happens:
1. Desired vertebral body height or angle is reached
2. Pressure reaches 30 atm
3. Volume reaches maximum
   – 4.5 ml for VBS Small
   – 5.0 ml for VBS Medium
   – 5.5 ml for VBS Large

Note: Stent expansion and pressure and volume on the VBS inflation system have to be monitored carefully.

Warning: Do not fill the balloons over their maximum volume or pressure. If this is done, they may leak.

Once the expansion is stopped, record the volume of solution used indicated on the inflation system.
Stent Insertion

5
Retrieve balloon catheters

To maintain maximum stent expansion, gradually decrease the pressure simultaneously on both sides. Slowly turn the handles of the inflation systems counter-clockwise to draw the liquid out of the balloon catheter (1). Once the pressure has reached 10 atm, push the white wings forward, slowly pull the handle back all the way, and release the white wings (2). This draws and holds a vacuum in the catheter and collapses the balloon for its removal.

Hold the working sleeves in place and pull firmly on the catheters to retrieve the balloons. Rotate the catheters if needed to ease balloon on removal. The stents remain in the vertebral body.

Verify the position of the bilaterally positioned stents under AP and lateral X-ray control.

Tip: If the stent expansion is inadvertently asymmetric or if a balloon leaks, the intact balloon catheter from the contralateral side can be reinserted in the vertebral body on the ipsilateral side and be repositioned in the stent and can be used for further expansion. Therefore, disconnect the inflation system from the balloon catheter, carefully insert the stiffening wire and replace the balloon catheter through the working sleeve in the vertebral body. Carefully monitor the insertion under lateral X-ray control. Stop insertion when the top end of the white range on the catheter shaft is aligned with the top of the working sleeve. Check the position under X-ray control and confirm the desired position under AP view. Ensure that the stent does not move during the replacement of the balloon catheter. Remove the stiffening wire and reconnect the inflation system, repeat the steps of creating a vacuum and re-inflate the balloon as described in this section.

Note: If the contrast medium/saline solution mixture leaks when the stents are expanded, it may be more difficult to remove the balloon catheters through the working sleeves. If necessary remove the balloon catheters together with the working sleeves or insert the stiffening wire for removal.
**Stent Augmentation**

1. **Inject PMMA based bone cement**

   Additional stent augmentation with a legally marketed PMMA based bone cement adequately indicated for use in vertebroplasty or kyphoplasty procedures is mandatory.

   After implantation of the stents, inject PMMA based cement bilaterally.

   Insert the side-opening cannulae into the working sleeves. Connect the syringes. The volume of cement required can be estimated from the volume of inflation medium needed for stent expansion (1).

   It is mandatory to monitor cement flow under real-time x-ray control.

   **Warning:** Cement should be injected until it infiltrates the surrounding bone around the stent. For safer cement application a high viscosity cement should be used (2).

   **Tip:** The side-opening cement outflow window can be closed by turning the cannula.

   It is recommended to use **Vertecem V+**.

   Vertecem V+ is a PMMA based bone cement to treat vertebral compression fractures:
   - Immediate injection upon mixing
   - About 27 minutes of working time
   - Excellent x-ray visibility

   **Note:** Refer to the manufacturer’s directions accompanying the bone cement for specific information on its use, precautions and warnings.
2
Remove side-opening needles and working sleeves

Wait until the cement has fully hardened. Observe the bone cement manufacturer’s instructions as the hardening times for PMMA based cements can greatly vary.

Usually instruments used for the cement injection can be removed approximately 2–3 minutes after the last injection of PMMA based bone cement by twisting the instrument assembly several times to sever the cement bridge.

Suture the wound with tight stitches for hemostasis.

Postoperative procedure
To compress the wound the patient should be placed in a supine position for an hour after surgery. Bruising may occur at the puncture sites. The patient can then be mobilized at discretion.

03.804.512S  Vertebral Body Stent Access Kit

- Contents:
  - 2× Cannulae with Side Opening, with Luer lock
  - 2× Injection cannulae with Luer lock
  - 2× Guide Wires, with Depth Markings
  - 2× Trocar
  - 2× Cannulated trocar
  - 2× Vertebral Body Stent Access Working Sleeve
  - 1× Vertebral Body Stent Access Drill
  - 1× Vertebral Body Stent Access Plunger

03.804.413S  VBS Inflation System
Optional Instruments

399.410 Hammer, 300 g

03.702.225S Biopsy Kit, for 8 Gauge Vertebral Body Stent Access Kit, sterile, pack of 1 unit

292.210S Kirschner Wire Ø 2.0 mm with trocar tip, length 280 mm, Stainless Steel, sterile

Vertecem V+ System

07.702.016S Vertecem V+ Cement Kit Containing:
1× Vertecem V+ Mixer pre-filled with cement powder
1× Monomer glass ampoule

03.702.215S Vertecem V+ Syringe Kit Containing:
8× Blue 1 ml syringes
5× White 2 ml syringes
1× one-way stop cock
